

Application Flow

Imagine you are implementing a 5 step application. The system needs to manage both the application progression flow and the user's current place within the application (ie they can come back and be dropped in where they left off). A user cannot skip any steps but should be allowed to go back to a previous step without losing their place within the application. When a user goes back to a previous step and submits that page, they should be redirected back to the furthest page within the application that they've seen.

What sorts of database models would you use to accomplish this? Please implement the GET and POST view handlers for a given step X which should contain the basic logic for setting the current step and getting the next step.

Attached are a few screenshots to give you an idea of what the front-end might look like.
